Individual reflection

Name: Pratik Dnyaneshwar Patil
Project: DA-01 Enterprise Business Intelligence Suite

What I owned: On the SQL side, I ran the warehouse schema, load procedure, views, and data quality test scripts, debugged the errors that came up, and validated the results. On the Power BI side, I built the relationships, the measures (Total Sales and Gross Margin %), the row-level security role, and the two report pages. For documentation, I filled in the test plan — the results, notes, and performance numbers — working from the test_plan.md file and checklist that were drafted for me, and I applied the load script fixes. Publishing to the Power BI Service and running the ADF pipeline are the next steps and were not completed.

What I learned:

SQL: I learned from running the data quality tests and reading the results rather than from writing them. The Gross Profit test failed, and the RLS check counted region keys instead of region names — both showed me that a test passing or failing tells you exactly where the data or the logic diverges from what you intended, and that you have to read the output carefully rather than assume it's right.

Power BI: I learned this concretely through the region problem. Every region bar came out the same length and a (Blank) bar appeared. The cause was that the active relationship controlled how the region filter reached the sales table, and it wasn't set correctly. Fixing the active relationship made the bars differ correctly. That taught me more about relationships than any general rule about cardinality would have.

Documentation: I learned that recording results and performance numbers in the test plan is as important as building the thing, because it forces you to define what "correct" actually means and show evidence that you checked it.
